

Question 1 · Across the blue stripe

Look at the pictures first. A short answer is enough; “cannot tell” is useful.

Do P and Q appear to be on two different beads?

Unmarked image

Same image, with P and Q

P = blue circle. Q = orange square. The yellow line joins the two marks.

It shows where I read the colors; it is not a proposed bead outline.

I put P beside the bright spot on the left, and Q on the blue area to the right of the dark stripe. I may be misreading either area.

Colors encountered along the line, from P → Q

Travelling from P to Q, the blue gets darker and then lighter.

That could be a gap between beads, but shading could do this too.

Your answer (choose one)

☐ Two beads

☐ One bead

☐ Cannot tell

Optional: if a mark is badly placed, say “move P left,” for example.

No coordinates, bead counts, or decisions about tiny fragments are needed.

Question 2 · The neighboring blue areas

Look at the pictures first. A short answer is enough; “cannot tell” is useful.

Do P and Q appear to be on two different beads?

Unmarked image

Same image, with P and Q

P = blue circle. Q = orange square. The yellow line joins the two marks.
It shows where I read the colors; it is not a proposed bead outline.

I put P below the central bright spot, and Q below the bright spot to its right. I want to check whether those are two separate beads.

Colors encountered along the line, from P → Q

Again, the blue darkens and then brightens along the line.
This supports looking for a boundary, but does not prove one.

Your answer (choose one)

☐ Two beads

☐ One bead

☐ Cannot tell

Optional: if a mark is badly placed, say “move P left,” for example.
No coordinates, bead counts, or decisions about tiny fragments are needed.

Supporting examples · What can mislead us

These explain the uncertainty. There are no extra questions on this page.

A bright spot can change color within one bead

This looks like one red bead.
The line goes through its highlight.

The sampled colors go from red
to almost white and back to red.

Lesson: a strong color change
does not by itself mark a boundary.

Along this line: red → white highlight → red

A badly placed starting point can mislead

This was my first attempt near
Question 2. P was too close to
the shadow stripe being tested.

The darkest part comes almost
immediately after P. I rejected
this placement; Question 2 uses
the revised pair of points.

Along the rejected line: the dark stripe is near the start

Only the wording and presentation have changed. These remain visual
hypotheses; no bead boundaries or inventory entries have been changed.
